Abstract: In this paper an improvement of the El-Gamal public key cryptosystem is presented. The public key of the El-Gamal system is not changed in this method. But, the sending structure of message and the decryption process are changed. The El-Gamal cryptosystem is not secure under adaptive chosen ciphertext attack. That means El-Gamal cryptosystem can be ciphertext attacked without knowing any key. Therefore changing keys of El-Gamal cryptosystem are not useful. This improvement cryptosystem immunes against CPA and CCA attacks. This cryptosystem is practical and very simple. The importance of this modified cryptosystem is any adversary can’t find the sending message in easily.

Keywords: public key cryptosystem, RSA public key cryptosystem, El-Gamal public key cryptosystem, Elliptic Curves Cryptosystem, chosen ciphertext attack, chosen plaintext attack

1 INTRODUCTION
Since the public key cryptography was introduced by Diffie and Hellman in 1976, designing Public Key Crypto Systems is very important research area in world. RSA cryptosystem, El-Gamal cryptosystem and Elliptic Curves cryptosystem are famous public key cryptosystems. But, there is no guarantee for the security of any cryptosystem yet. For an example anyone can attack to the ciphertext of El-Gamal cryptosystem without knowing any keys. Many countries are trying to find a better cryptosystem and fund more to research projects based on cryptography. There are many public key cryptosystems have been developed in world. But, we can’t trust 100% none of those systems.

I describe here briefly the definition of public key cryptosystem and two famous public key cryptosystems in world, the RSA public key cryptosystem and the El-Gamal public key cryptosystem.

1.1 Definition:
A public key cryptosystem is a tuple of probabilistic polynomial –time algorithm (Kgen, Enc, Dec) such that:

1. Kgen is a probabilistic key generation algorithm that takes as input 1k for a security parameter k ∈ ℵ and returns a public key pk and a secret key sk. The public key pk defines a space M, called message space.
2. Enc is a probabilistic algorithm that takes as input a public key pk and a message m ∈ M and returns a ciphertext c.
3. Dec is a deterministic algorithm that takes as input a secret key sk and a ciphertext c, and returns a message m or the reject symbol ⊥. Moreover a further fundamental property is required: correctness. We want that for every k ∈ ℵ , every pair (pk, sk) ← Kgen(1k), and for every message m ∈ M , the following equation holds:
   \[ \Pr[\text{Dec}(sk,Enc(pk,m)) = m] = 1. \]

1.2 RSA public key cryptosystem
This public key cryptosystem was introduced by R.L. Rivest, A. Shamir and L. Adleman in 1978. This system was the first practical public key cryptosystem. Following is the RSA scheme.

1. Two large prime numbers are generated. Let p and q.
2. Modulus n is generated by multiplying p and q.
3. The totient of n is φ(n) = (p-1)(q-1) is calculated.
4. Public Key: A prime number e is selected. where 3 ≤ e ≤ φ(n) and gcd [e, φ(n)] = 1; gcd means greatest common divisor.
5. Private Key: The inverse of e with respect to mod φ(n) is calculated.

The RSA function for message m and key k is,
\[ F (m, k) ≡ m^e \mod n \]
Encryption: \[ m^e \mod n \equiv c \]
Decryption: \[ c^d \mod n \equiv m \]

Example: Let p = 7 and q = 11.
Then n = 77 and φ(n) = 60.
Choose e = 13. gcd [e, φ(n)] = 1.
Then the secret key d can find easily. e.d = 1 mod φ(n)
That means 13.37 = 1 mod 60. Hence, d = 37.
Let the message is m = 6.
Encryption: \[ m^e \mod n \equiv 6^{13} \mod 77 \equiv 62 \equiv c \]
Decryption: \[ c^d \mod n \equiv 62^{37} \mod 77 \equiv 69 \equiv m \]

The security of RSA is based on the infeasability of factorization large n.

1.3 The El-Gamal cryptosystem
This public key cryptosystem was introduced by Taher Elgamal in 1985.

Step 01: Global elements: Let any large prime number p and a primitive root g of p.
Step 02: Decryption key: x – private, Calculate \( g^x \mod p \), where \( x \in \mathbb{Z} \).
Publish \( (p, g, g^x \mod p) \).
Step 03: Encryption:
Let the message is \( m \); (0 < m < p) and choose random \( y \) - private (0 < y < p).
Compute \( b = g^y \mod p \). Then,
\[ c \equiv m.a^y \mod p. \]
Send \( (b, c) \).
Step 04: Decryption:
Compute \( b^y \mod p \equiv a^y \). Then,
\[ m \equiv a^{x-y}.c \mod p. \]

Example:
Step 01: Select \( p = 23 \) and a primitive root of \( p = 23 \) is \( g = 5 \).
Step 02: Let, \( x = 8 \).
Calculate \( g^x \mod p \equiv 5^8 \mod 23 \equiv 16 \).
Publish \( (23, 5, 16) \).
Step 03: Encryption:
Let the message is \( m = 6 \); and choose \( y = 3 \)
1.4 A chosen ciphertext attack on El-Gamal public key cryptosystem

The El-Gamal system is not secure under Chosen Ciphertext Attack. Anyone can easily get the message.

Example:
Global elements: Large prime number $p$ and a primitive root $g$ of $p$.
Decryption key: $x – private$. Calculate $a \equiv g^x \mod p$ , where $x \in \mathbb{Z}$.
Publish $(p, g, a)$.

Encryption:
Let the message is $m$; $0 < m < p$) and choose $y - private (0 < y < p)$.
Compute $b = g^y \mod p$. Then, $c \equiv m \cdot a^y \mod p$.
Send $(b, c)$.

In decryption process $m^\prime$ is divide by the attacker. Note that all are considered in $mod p$.

Let the ciphertext is $C = (b, c)$.

$$C = (b, c) = (g^y, m \cdot a^y)$$

Now calculate $C^\prime$ by the attacker as follows:

$$C^\prime = (g^y g^k, a^y m.a^k, m')$$

Give, $C^\prime$ to the decryption oracle.

$m^\prime$ will be return.

Now we can get $m$ from $m^\prime$.

$$C^\prime = (m, m'), a^{xy + k}$$

$m^\prime = m \cdot m^{-1}$

Therefore we can get the message easily without any keys.

2 PROPOSED IMPROVEMENT OF THE EL-GAMAL PUBLIC KEY CRYPTOSYSTEM

I proposed an improvement for the El-Gamal public key cryptosystem. In this paper, I get the message in numerical form. But, we can get any standard representation for a large message.

Consider we have to encrypt a message $m$. In this method, the public encryption key is $(p, g, g^x \mod p)$. Here $p$ is any large prime number and $g$ is a primitive root of $p$. The public encryption key is similar to the public encryption key of the El-Gamal public key cryptosystem.

The structure of the ciphertext $C$ has changed on the improvement system. Write $m = p_1 p_2 p_3 \ldots p_i$; Where $p_i$ is prime. $(0 < i < P)$. That means we need $i$ prime numbers as products to get $m$. Then $(g^x \mod p)^y \mod p$ is multiplied by the number of prime numbers which needs to get $m$. $c$ is calculated by the $i$ th power of the message $m$. Then we send $(g^x \mod p, m, i, g^x \mod p)$. In decryption process first $(g^x \mod p, m, i, g^x \mod p)$. If the decryption process is $g^x \mod p = (g^x \mod p)^y$ is calculated. Then $i.(g^x \mod p)^y \mod p$. This is divided by $(g^x \mod p)^y$. Now we have $i$. Then taking the inverse of $i$ on $c$ we can get the message $m$.

You can use this system with following steps.

Step 01: Global elements: Let any large prime number $p$ and a primitive root $g$ of $p$. $p \neq 0$.

Step 02: Decryption key: $x – private$, Calculate $g^x \mod p$, where $x \in \mathbb{Z}$.
Publish $(p, g, g^x \mod p)$.

Step 03: Encryption Process:
Let the message is $m$; $(0 < m < p)$ and choose $y - private (0 < y < p)$.
Compute $b = g^y \mod p$.
Write $m = p_1 p_2 p_3 \ldots p_i$; Where $p_i$ is prime. $(0 < i < P)$
Calculate $n = i, a^x \mod p$
Calculate $c = m^i$
Send $(b, c, n)$

Step 04: Decryption:
Compute $b^x \mod p \equiv a^y$. Then,
Calculate $\frac{n}{b^x \mod p}$
(Note : $\frac{n}{b^x \mod p} = i$

$$m = c^{1/i}$$

2.1 Proof
The extended El-Gamal system decryption expression is:

$$c^{-n} = \frac{g^{xy} \mod p}{g^{x^y} \mod p} \equiv \frac{g^{xy^y} \mod p}{g^{xy} \mod p} \equiv c^{1/i} \equiv (m^i)^{1/i} = m$$

2.2 Procedure
Let the public key is $(g, a, p)$ and the ciphertext is $(b, c, n)$. See the figure 01.

2.3 Key Generation for the Extended El-Gamal system

Key generation of the extended El-Gamal system is same as the El-Gamal public key cryptosystem.

Algorithm

Extended_ElGamal_Key_Generation
{
Select a large prime $p$
Select $x$ to be a member of the group $(\mathbb{Z}_p^+, \times)$; $1 \leq x \leq p - 2$
Select $g$ to be a primitive root in $(\mathbb{Z}_p^+, \times)$
$a \leftarrow g^x \mod p$
Public_key $\leftarrow (g, a, p)$
Private_key $\leftarrow d$
return Public_key and Private_key
}

2.4 Extended El-Gamal Encryption

Algorithm

Extended_ElGamal_Encryption $(g, a, p, i, m)$
{
Select a random integer $y$ in the group $(\mathbb{Z}_p, \times)$
$b \leftarrow g^y \mod p$
$n \leftarrow L a^x \mod p$
c $\leftarrow m^i$

www.ijcat.com
2.5 Extended El-Gamal Decryption

Algorithm

Extended_ElGamal_Decryption (x, p, b, n, c)
{
    b = g^y mod p
    n = i.a^y mod p
    m = c \equiv \frac{n}{b^x \mod p}
    return m
}

2.6 Computational complexity

If we use the fast exponential algorithm then encryption and decryption of the extended system can be done in polynomial time.

2.7 Examples for the improved system

Example 01:
Step 01: Select p = 23 and a primitive root of p = 23 is g = 5.
Step 02: Let, x = 8.
    Calculate g^x mod p ≡ 5^8 mod 23 ≡ 16.
    Publish (23, 5, 16).
Step 03: Encryption:
    Let the message is m = 6; and choose y = 3.
    Compute a = b ≡ g^y mod p ≡ 5^3 mod 23 ≡ 10.
    Write m = 2 \times 3; Then, i = 2
    Calculate n = i.a^y mod P ≡ 2.16^3 mod 23 ≡ 4
    Calculate c = m^i ≡ 6^2 ≡ 36
    Send (b, c, n) = (10, 36, 4).
Step 04: Decryption:
    Compute b^x mod p ≡ 10^8 mod 23 ≡ 2. Then,
    Calculate \frac{n}{b^x \mod p} = \frac{42}{2} = 2
    (Note : \frac{n}{b^x \mod p} = i)
    m = c^i = 36^{1/2} = 6

Example 02:
Step 01: Select p = 71 and a primitive root of p = 71 is g = 7.
Step 02: Let, x = 25.
    Calculate a = g^x mod p ≡ 7^{25} mod 71 ≡ 41
    Publish (71, 7, 41).
Step 03: Encryption:
    Let the message is m = 27; and choose y = 9.
    Compute b ≡ g^y mod p ≡ 7^{9} mod 71 ≡ 47.
    Write m = 3 \times 3 \times 3; Then, i = 3
    Calculate n = i.a^y mod P ≡ 3.41^9 mod 71 ≡ 69
    Calculate c = m^i ≡ 27^3 ≡ 19683
    Send (b, c, n) = (47, 19683, 69)

Step 04: Decryption:
    Compute b^x mod p ≡ 47^{25} mod 71 ≡ 23. Then,
    Calculate \frac{n}{b^x \mod p} = \frac{69}{23} = 3
    (Note : \frac{n}{b^x \mod p} = i)
    m = c^i = 19683^{1/3} = 27

3 THE IMMUNITY FOR A CHOSEN CYPHERTEXT ATTACK

Global elements: Let any large prime number p and a primitive root g of p.

Decryption key: x - private, Calculate g^x mod p, where x ∈ Z.
    Publish (p, g, g^x mod p).

Encryption Process:
    Let the message is m; (0 < m < p) and choose y - private (0 < y < p).
    Compute b ≡ g^y mod p.
    Write m = p_1 \cdot p_2 \cdot p_3 \ldots p_i; Where p_i is prime. (0 < i < p)
    Calculate n = i.a^y mod p
    Calculate c = m^i
    Send (b, c, n).

Now the attacker gets the ciphertext C = (b, c, n).

Attacker chooses values k, m' and t randomly. (According to previous attack to the El-Gamal public key cryptosystem, the attacker chooses only two random values. From two values he can never attack to this extended system. So, the attacker chooses 3 values to attack to this extended system).

C = (b, c, n)
= (g^x \cdot m^t, i.a^y mod p)
Now calculate $C'$ by the attacker as follows:

$$C' = (g^{y^i} g^{k}, \ m^i.m^i, \ .a^y \ \text{mod} \ p. \ .t.a^k \ \text{mod} \ p. \ )$$

$$C' = (g^{y^i+k}, \ m^i.m^i, \ (i.t). (a^y \ \text{mod} \ p, \ (a^k \ \text{mod} \ p) \ ) \ $$

Give, $C'$ to the decryption oracle.

$m''$ will be return.

$$m' = m^i.m^i \ \text{mod} \ p$$

$m = \left(\frac{m'}{m}\right)^{1/i}$

The attacker does not know the value of $i$. Therefore he can’t get $m$ from $m''$.

So, above ciphertext attack will be failure in this extended El-Gamal system.

4 SECURITY OF THE IMPROVED PUBLIC KEY CRYPTO SYSTEM

4.1 Notions of Security

Semantic Security (indistinguishability of Encryptions/ IND): This notion was introduced by Goldwasser and Micali [12]. This property captured the idea according to which an adversary should not be able to get any information about a plaintext, its length excepted given its encryption.

Chosen Plaintext Attack (CPA): The adversary can access an encryption oracle and hence to the encryption of any plaintext.

Non-Adaptive Chosen Ciphertext Attack (CCA1/ Lunchtime Attack/ Midnight Attack): The adversary can access a decryption oracle before being given the challenge ciphertext.

Adaptive Chosen Ciphertext Attack (CCA2): According to Rackoff and Simon [13], the adversary queries the decryption oracle before and after being challenged. But, the adversary may not feed the oracle with the challenge ciphertext itself.

4.2 IND-CPA security of the improved El-Gamal cryptosystem

This improved cryptosystem is IND-CPA secure as IND-CPA security of El-Gamal public key cryptosystem.

Discrete Diffie-Hellman Assumption:

The tuple $(g^x, \ g^y, \ g^{xy})$ is computationally indistinguishable from $(g^x, \ g^y, \ g^z)$ for $x, \ y, \ z \ \in \ \mathbb{Z}_q$.

Theorem: If the Discrete Diffie-Hellman problem is hard then the improved El-Gamal cryptosystem is IND-CPA secure.

Proof: (By contradiction). Assume that an adversary can break the improved El-Gamal cryptosystem. That is, it has significant advantage by a real or random definition,

$$AdvA = \Pr[A^{F_E}(pk) = 1] - \Pr[A^{F_{E^A}}(pk) = 1].$$

Since improved cryptosystem is a public key encryption scheme, if it is secure against a single query it is secure against $q$ queries, so we only need to show that it is $(t, q, e)$ secure for $q = 1$; we can thus assume that the adversary $A$ makes exactly one query. The adversary $A$ that runs in time $t$ and has advantage $\delta$, we can construct another adversary $B$ for DDH that runs in time $t + O(1)$ and has advantage $\delta$. Algorithm $B(a, b, c)$ is as follows:

1. Run $A^{E_E}(a)$, where $B$’s version of the encryption oracle $E_g$ answers its one query $m$ with $(b, c, m)$.
2. Output the same result as $A$ does.

In the case where $B$ is called on a triple of the form $(g^x, \ g^y, \ g^{xy})$. What $A$ sees is identical to interacting with a real encryption oracle $B(g^x, \ g^y, \ g^{xy}) = A^{F_E}(pk)$. In the case where $B$ is called on a tuple of the form $(g^x, \ g^y, \ g^{xy})$. A sees the values $a = g^x$ and $(b, c, m) = (g^y, g^z, m)$. Since $g^x$ is selected uniformly at random, $g^y, m$ is also a uniform random value and is thus completely indistinguishable from $g^{xy}$. So $(m)$ and $(g^y, g^z, m)$ is the same distribution as $g^x, g^y, g^z$. $\delta(m)$. This makes $B$ a perfect simulator of a random oracle and in this case $B(g^x, g^y, g^z) = A^{F_{E^A}}(pk)$.

This construction thus turns an adversary that breaks Extended El-Gamal cryptosystem into one that breaks DDH with the same advantage, adding constant time complexity.

5 CONCLUSIONS AND FUTURE WORKS

An improvement of El-Gamal public key cryptosystem has presented. The security of this improved system depends on $\ell$. If anyone gets $\ell$ then he can find the message easily. In this system the encryption increases the size of a message. Therefore this improved system is very suitable for small messages or key exchanges.

I try to solve the problem that is the encryption increases the size of a message of above introduced system, using modular exponentiation methods.

6 ACKNOWLEDGEMENT

I would like to thank Dr. Sandirigama, M. (Department of Computer Engineering, Faculty of Engineering, University of Peradeniya, Sri Lanka), Dr. Ishak, A. M.I.M. (Department of Engineering Mathematics, Faculty of Engineering, University of Peradeniya, Sri Lanka) and Dr. Alawathugoda, A. J. (Department of Computer Engineering, Faculty of Engineering, University of Peradeniya, Sri Lanka) for their very useful advice in my research work.
